Question:

Find the minimum and maximum values of the given function:

$$f(x) = |\sin(4x) + 3|$$

THEORETICAL METHOD

We analyze the function theoretically to find its critical points. Let:

$$f(x) = |g(x)|, \quad g(x) = \sin(4x) + 3 \quad (0.1)$$

The critical points of $g(x)$ occur where $g'(x) = 0$. Differentiating $g(x)$:

$$g'(x) = 4 \cos(4x) \quad (0.2)$$

Setting $g'(x) = 0$, we find:

$$\cos(4x) = 0 \implies 4x = \frac{\pi}{2} + n\pi \implies x = \frac{\pi}{8} + \frac{n\pi}{4}, \quad n \in \mathbb{Z} \quad (0.3)$$

For these x -values, we calculate $g(x)$ to find the maximum and minimum values of $|g(x)|$:

$$g(x) = \sin(4x) + 3, \quad f(x) = |g(x)| \quad (0.4)$$

At the critical points, evaluate $f(x)$ directly to determine the local maximum and minimum values. The function $f(x)$ achieves its minimum value at $f(x) = 3$ and maximum value at $f(x) = 4$.

COMPUTATIONAL METHOD

We use gradient descent to find the minima and maxima numerically. Gradient descent works iteratively using the following update rule:

$$x_{n+1} = x_n - \mu f'(x_n) \quad (0.5)$$

The gradient $f'(x)$ is computed numerically as:

$$f'(x) \approx \frac{f(x + \delta) - f(x - \delta)}{2\delta} \quad (0.6)$$

Algorithm Steps:

- **Initialize:** Start with an initial guess for x , a step size (μ), and a threshold for convergence.
- **Update:** Compute $f'(x_n)$ and update x_n using the update rule.
- **Convergence:** Stop when $|f'(x_n)| < \text{threshold}$.

Results: Using an initial guess $x = 0$, step size $\mu = 0.01$, and threshold $1e - 5$, the numerical method yields:

$$x_{min} = 0.785398, f(x_{min}) = 3.000000 \quad (0.7)$$

$$x_{max} = 0.392699, f(x_{max}) = 4.000000 \quad (0.8)$$

Thus, the maximum value of $f(x)$ is 4, and the minimum value of $f(x)$ is 3. These values match the theoretical results.
